METRIC SYSTEM OF WEIGHTS AND MEASURES

Statistics of so many countries are now expressed in terms of the Metric System that for intelligent reading a knowledge of the relative American measures for such figures is indispensable. A distance expressed in kilometers conveys no definite idea to the American reader who does not know how the kilometer compares with a mile. Similarly, when we read that 10,000 myrialiters of crude oil are destroyed by fire in Armenia, we cannot tell whether the loss is 1,000 gallons or 10,000 barrels unless we know the American equivalent for a liter or myrialiter. For this reason we give below a brief explanation of the Metric System.

The Metric System of Weights and Measures originated in France. Its use is required by law, in many countries; in many others, including the United States, Canada, and Great Britain, its use is optional. For scientific as distinguished from commercial purposes, it is now commonly employed throughout the world.

The fundamental unit on which the entire system is based is the *meter*, which is a unit of length. The meter is a *natural* unit, the *ten-millionth part of the meridian distance between the equator and the north pole*. Its length in inches has been determined as accurately as possible by the actual measurement of an arc of a meridian, and is found to be 39.37079 inches (or approximately 39.37 inches, the legal equivalent for all standardizing and reductions).

Although the meter is a unit of *length* only, all the other units of the Metric System are derived from it. The cube of the tenth part of the meter (cubic decimeter) is taken as the unit of *capacity*, and called a *liter*. The cube of the hundredth part of the meter (cubic centimeter) measures the volume of a quantity of distilled water (of maximum density) whose weight is taken as the unit of *weight*, and called a *gram*. The unit of square measure or *area* of surface is a square with sides of 10 meters, called an *are;* and the cube of the meter is a unit of volume called a *stere*. All other denominations are the decimal subdivisions or multiples of these units. The names of these subdivisions and multiples are formed by combining the words "meter," "gram," "liter," etc., with Greek and Latin prefixes. To indicate subdivisions, the Latin prefixes *deci-*, *centi-*, and *milli-* are used; multiples, on the other hand, are indicated by the Greek prefixes *deka-*, *hecto-*, *kilo-*, and *myria-*, as follows:

PREFIXES (for Subdivisions)	PREFIXES (for Multiples)
deci- = *one-tenth*	deka- = *ten*
centi- = *one-hundredth*	hecto- = *one hundred*
milli- = *one-thousandth*	kilo- = *one thousand*
	myria = *ten thousand*

For example, a decimeter = one-tenth meter; a centimeter = one-hundredth meter; a dekameter = 10 meters; a milligram = one-thousandth gram; a kilogram = 1,000 grams; a centiliter = one-hundredth liter; a hectoliter = 100 liters; and so on.

The *meter* is a unit of length similar to our *yard;* and as the yard contains 36 inches, and the meter 39.37 inches, a meter may always be thought of as being approximately 1⅒ yards. This will be near enough for most mental calculations. For instance 10 kilometers, which is 10,000 meters, would equal approximately 11,000 yards.

A cubic decimeter is called a *liter*. It is the unit of capacity, and equals 61.027051519 cubic inches. The *gallon*, the American unit of capacity, contains 231 cubic inches. A quart, or one-fourth of a gallon, therefore, contains 57.75 cubic inches, so that a liter contains just a trifle over one quart. Thus the 10,000 myrialiters or 100,000,000 liters of oil burned in Armenia would equal a little more in round numbers than 105½ million quarts, or 26⅜ million gallons, or approximately 630,000 barrels of 42 gallons each.

The unit of weight in the Metric System is a cubic centimeter of distilled water, and is called a *gram*. It weighs in American measure .00220462 lb. avoirdupois. A gram is therefore equal to a little more than two one-thousandth parts of our pound avoirdupois; therefore, if we think of 450 grams as being approximately one pound it will ordinarily come near enough for mental calculations.

The metric unit of what we call square measure is the square of 10 meters, or 100 square meters, and is called an *are*. One square meter equals 10.763087 square feet in American measure, or 1.195985 square yards, approximately 1⅕ square yards.

The unit of cubic measure in the Metric System is the *stere*, which is the cube of the meter; and one stere or one cubic meter equals 1.30794 cubic yards or about 1⅓ cubic yards.

From the above the relative amount in American measure can readily be computed for anything expressed in metric terms. The figures in the examples are in most instances only approximate, and are intended for mental calculations rather than exact computation.

One of the great advantages of the Metric System is the simplification of the process of reduction of quantities. All denominations being decimal parts or multiples of others in the ascending or descending scale, reductions and calculations are largely accomplished by merely taking care of the decimal point.

AMERICAN AND FOREIGN MONEY VALUES

All statistics in this Atlas indicating the value of the production, exports, imports, etc., of various countries, are expressed in dollars and cents—the common standard units of value intelligible to everyone. The reader, however, will find many instances elsewhere—in newspapers, in books, in foreign bulletins, and even in many of the official reports published by our own Government—where no reduction to American standards has been made. To anyone not perfectly familiar with the comparative values of foreign and American monetary units, it conveys no clear idea to be told, for example, that the onion crop of Egypt in 1920 was valued at a certain number of pounds Egyptian (£E), or that Germany's exports for the first five months of 1920 amounted to over 24 billion marks. The table below will, therefore, serve a very helpful purpose.

The values indicated in the table are the standard values at *par of exchange* as determined by the Secretary of the United States Treasury, and are subject to alteration only by his official proclamation. These standard values may differ very materially from the *current exchange or market values*, which are more or less dependent on the prevailing condition of the balance of trade in any particular country and which may also fluctuate with their political unrest and degree of internal stability, etc. The German mark, for example, March 24, 1922, was quoted at .3 cent; and the Russian ruble, at an infinitesimal fraction of a cent.
